Pharmacotherapy Review Program for Advanced Clinical Pharmacy Practice

Workbook Key

March 26–28, 2012
Kuala Lumpur, Malaysia

American College of Clinical Pharmacy
Lenexa, Kansas
United States of America
Material appearing in this workbook is adapted from matter originally published in the following chapters:

# Table of Contents

Nephrology ................................................................. 1  
*Alan Lau, Pharm.D., FCCP*

Endocrinology ............................................................. 5  
*Zachary A. Stacy, Pharm.D., BCPS*

Biostatistics and Clinical Trial Design and Interpretation ....................... 13  
*Robert DiCenzo, Pharm.D., FCCP, BCPS*

Infectious Diseases in the Ambulatory Care Setting .................................. 19  
*Brian A. Hemstreet, Pharm.D., BCPS*

Infectious Diseases in the Inpatient Setting ............................................. 24  
*Brian A. Hemstreet, Pharm.D., BCPS*

Cardiology ................................................................. 26  
*Zachary A. Stacy, Pharm.D., BCPS*

Gastrointestinal Diseases .......................................................... 32  
*Brian A. Hemstreet, Pharm.D., BCPS*

Pulmonary Diseases ............................................................. 35  
*Brian A. Hemstreet, Pharm.D., BCPS*
Program Goals

The Pharmacotherapy Review Program for Advanced Clinical Pharmacy Practice is designed to help pharmacists who are preparing for the Board of Pharmacy Specialties certification examination in Pharmacotherapy as well as those seeking a general review and refresher on pharmacotherapeutics and clinical skills.

Program goals are to:

1. present a high-quality, up-to-date overview of pharmacotherapeutics;
2. provide a framework to help participants prepare for the pharmacotherapy specialty certification examination; and
3. engage participants in an interactive, case-based learning experience to advance the clinical judgment and problem-solving skills required in clinical practice.
Faculty

Robert DiCenzo, Pharm.D., FCCP, BCPS
Professor and Chair
Department of Pharmacy Practice
Albany College of Pharmacy & Health Sciences
Albany, New York

Brian A. Hemstreet, Pharm.D., BCPS
Associate Professor
University of Colorado
Skaggs School of Pharmacy and Pharmaceutical Sciences
Aurora, Colorado

Alan H. Lau, Pharm.D., FCCP
Professor
Director, International Clinical Pharmacy Education
College of Pharmacy
University of Illinois at Chicago
Chicago, Illinois
Professional Development Associate – International Programs
American College of Clinical Pharmacy
Lenexa, Kansas

Zachary A. Stacy, Pharm.D., BCPS
Associate Professor of Pharmacy Practice
St. Louis College of Pharmacy
St. Louis, Missouri
Nephrology

Renal Function Assessment

1. **Answer: D**
   An elderly sedentary woman does not likely have much muscle mass, the source of creatinine (Cr). In the Cockcroft-Gault equation, serum creatinine (SCr) is in the denominator; consequently, a very low value (0.4 mg/dL) will make the final calculated value very high...probably much higher than the actual glomerular filtration rate (GFR).

Acute Kidney Injury

2. **Answer: D**
   Estimating the creatinine clearance (CrCl) in a patient with unstable kidney function is difficult. The Jeliffe or Brater equation has been recommended as preferable to other equations. In this case, the patient is anuric; hence, a CrCl (GFR) of 10 mL/minute or less (Answer D) should be assumed. Answer A (Cockcroft-Gault) is inappropriate because Cockcroft-Gault should only be used with stable kidney function. The use of the Modification of Diet in Renal Disease (MDRD) (study) (Answer B) in unstable kidney function is also inappropriate. Although Answer C, the Brater equation, may be used, it would still overestimate kidney function in this patient because the patient is anuric.

3. **Answer: B**
   This patient very likely has acute tubular necrosis (ATN), which is a type of intrinsic renal failure (Answer B). The rapid rise in SCr, the blood urea nitrogen (BUN)/Cr ratio of about 10, and the muddy casts all point to ATN. There is no evidence of prerenal causes (hypotension, volume depletion) (Answer A). Naproxen is associated with functional acute kidney injury (AKI), but the urine of patients with AKI is bland without casts. Answer C is incorrect because there is no evidence of obstruction in this patient.

4. **Answer: D**
   One strategy in the management of AKI is to remove potentially nephrotoxic drugs, either direct toxins or medications that alter intrarenal hemodynamics. It is common to see the following orders for patients with AKI: no angiotensin-converting enzyme inhibitors (ACEIs), angiotensin receptor blockers (ARBs), nonsteroidal anti-inflammatory drugs (NSAIDs), or intravenous contrast. It is also important to remove (or reduce the dose of) agents that are cleared renally. Metformin, which accumulates in decreased kidney function with an increased risk of lactic acidosis, should be temporarily discontinued at this time. In this case, metformin, naproxen, and lisinopril should be discontinued.

5. **Answer: C**
   This patient presents with ATN, anuria, and volume overload. Although loop diuretics have not been shown to improve clinical outcomes in patients with AKI, they may increase urine output, which will help with fluid and electrolyte balance. In addition, this patient is hypervolemic, so a trial of
intravenous loop diuretic would be appropriate (Answer C). Adding 0.9% sodium chloride (NaCl) (Answer A) would worsen fluid overload. Hydrochlorothiazide (Answer B) would not be appropriate because thiazide diuretics are not likely to be effective with such poor kidney function. Fluid restriction (Answer D) may be required if furosemide fails to increase urine output, but it would not be the first-line approach.

**Drug-Induced Kidney Damage**

6. **Answer: B**  
Intravenous 0.9% NaCl is considered the most effective hydration for the prevention of contrast-induced nephropathy (Answer B). The other solutions, particularly the oral solution, would not be appropriate.

7. **Answer: B**  
Many data have been published on the use of oral acetylcysteine in the prevention of contrast-induced nephropathy. Although many of the studies are observational and some are conflicting, the low risk of the product has made it the standard of care in this situation. Fenoldopam (Answer A) should not be used on the basis of the results obtained in the CONTRAST trial. Although some data exist with ascorbic acid (Answer C), they are limited. Hemofiltration (Answer D) has also been studied, but it is not generally recommended because of the questionable benefits and the real risk of complications.

**Chronic Kidney Disease (CKD)**

8. **Answer: B**  
The patient is currently at stage 3 CKD (GFR 30–59 mL/minute/1.73m²), which can be calculated by the MDRD formulae or Cockcroft-Gault. The five stages correlate from mild kidney damage (stage 1) to kidney failure (stage 5).

9. **Answer: C**  
On the basis of this patient’s diabetes mellitus diagnosis and overt proteinuria, the patient likely has diabetic nephropathy. Progression will be accelerated by smoking, poor diabetes control, and poor blood pressure (BP) control. In patients with diabetes, a target hemoglobin A\textsubscript{1c} of less than 7% is associated with a decrease in the rate of disease progression. Blood pressure control of less than 130/80 mm Hg in patients also decreases the progression of kidney disease. The standard of care in patients with diabetic nephropathy is ACEIs (evidence for a reduction in morbidity and reduced progression of CKD) or ARBs (evidence for a reduction in progression but no mortality data), so enalapril (Answer C) is the best choice. A nondihydropyridine (Answer B) might be initiated in patients who cannot tolerate ACE or ARB therapy but would not be a first choice. Dihydropyridine therapy (Answer A) is not recommended in diabetic nephropathy because of conflicting literature on its efficacy. An increase in atenolol (Answer D) might control BP, but inhibition of the renin-angiotensin system is still the best answer. In addition, a recent meta-analysis evaluating atenolol in hypertensive patients with diabetes mellitus found either no difference in outcomes or worse outcomes.
10. Answer: B
The BP is not at goal (should be less than 130/80 mm Hg). To improve BP control and enhance the effect of the ACEI, chlorthalidone should be added to the regimen (Answer B). Monitoring of Scr and serum potassium is appropriate in this patient. There is less than a 30% increase in Scr, so enalapril should be continued, making Answers A and C inappropriate. Adding chlorthalidone would also counter the tendency for hyperkalemia. Answer D would probably lower BP but would not be the preferred route because renal protection would likely not be enhanced.

11. Answer: D
The amount of potassium in that much orange juice could be lethal because most patients with stage 5 CKD are already hyperkalemic and have no way to eliminate potassium. Although ingesting too much sodium (Answer A) or fluid (Answer C) is bad, it is not likely lethal. Aluminum toxicity (Answer B) takes years to develop and is not acutely toxic.

12. Answer: B
Hyperparathyroidism is associated with epoetin resistance in patients on hemodialysis (HD) (Answer B). Although iron deficiency is the most common cause of epoetin deficiency, the laboratory results for this patient do not indicate iron deficiency (Answer A). Phenytoin therapy (Answer C) has been associated with anemia in other patient populations, but not in HD patients. Infection (Answer D) and inflammation are very common causes of epoetin deficiency in patients on HD, but there is nothing in this patient's presentation to suggest an infectious or inflammatory process.

13. Answer: B
D.W. requires treatment for his elevated immunoreactive parathyroid hormone (iPTH) (800 pg/dL), which puts him at high risk of renal osteodystrophy. He has high serum phosphorous and calcium. The corrected calcium is 10.2 mg/dL, and the calcium × phosphorus factor is 80 mg²/dL². The goal/target calcium × phosphorus factor in stage 5 CKD is less than 55 mg²/dL². Current binder therapy is contributing to calcium exposure; therefore, calcium acetate should be discontinued and sevelamer initiated. Cinacalcet will lower the iPTH and potentially serum calcium. Answer A is incorrect because increasing the calcium acetate may worsen the hypercalcemia. Answer C is incorrect for two reasons. First, the patient needs some type of phosphate binder; second, intravenous vitamin D analogs can worsen hypercalcemia and are not very effective at reducing elevated iPTH in the presence of hyperphosphatemia. Answer D is incorrect because intravenous vitamin D analogs can worsen hypercalcemia and are not very effective at reducing elevated iPTH in the presence of hyperphosphatemia.

14. Answer: A
The target hemoglobin in these patients should not be normal. All prospective studies find that trying to normalize hemoglobin with ESAs (erythropoiesis-stimulating agents) results in worse outcomes. The hemoglobin target, as recommended by the FDA (U.S. Food and Drug Administration) (since June 2011), should not be greater than 10 g/dL. Use the lowest dose of ESA sufficient to reduce the need for RBC (red blood cell) transfusions. The other answers are all true.
15. **Answer: D**

A native arteriovenous fistula is the preferred access for long-term HD. If an arteriovenous fistula cannot be constructed, a synthetic arteriovenous graft (Answer C) is considered second line. A subclavian catheter (Answer A) is a poor choice because of the increased risk of infection and thrombosis and because of the poor bloodflow obtained through a catheter. A Tenckhoff catheter (Answer B) is incorrect because it is for peritoneal dialysis.

16. **Answer: D**

The best-studied agent is midodrine, an $\alpha_1$-agonist. Levocarnitine (Answer A) has been tried, but there are limited data on its benefit. Fludrocortisone (Answer C) is a synthetic mineralocorticoid, which is used for hypotension in other situations; however, the primary mechanism is caused by Na and water restriction in the kidney; hence, this drug is less likely to work. Sodium chloride tablets (Answer B) would not work acutely and should generally be avoided.

17. **Answer: B**

The presence of kidney failure and low albumin results in an increased free fraction of phenytoin. Using the correction equation gives a corrected level of 12.5, which is therapeutic. A free phenytoin concentration can also be drawn.
## ENDOCRINOLOGY

### Activity 1: Diabetes Mellitus Diagnostic Criteria

1. Criteria for diagnoses

<table>
<thead>
<tr>
<th></th>
<th>Normoglycemia</th>
<th>Prediabetes</th>
<th>Diabetes</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPG</td>
<td>&lt; 100 mg/dL</td>
<td>100–125 mg/dL</td>
<td>≥ 126 mg/dL a</td>
</tr>
<tr>
<td>PPG (after 75 g OGTT)</td>
<td>&lt; 140 mg/dL</td>
<td>140–199 mg/dL</td>
<td>≥ 200 mg/dL a</td>
</tr>
<tr>
<td>Random PG</td>
<td></td>
<td></td>
<td>&gt; 200 mg/dL + symptoms a</td>
</tr>
<tr>
<td>Hemoglobin A1c</td>
<td>&lt; 5.7%</td>
<td>5.7%–6.4%</td>
<td>≥ 6.5% a</td>
</tr>
</tbody>
</table>

*aShould be confirmed by repeat test (preferably the same test) on a different day.  
FPG = fasting plasma glucose; OGTT = oral glucose tolerance test; PG = plasma glucose; PPG = postprandial blood glucose.

### Activity 2: Type 2 Diabetes Mellitus

2. This patient has the following American Diabetes Association risk factors for type 2 diabetes mellitus (DM):

- Age older than 45 years
- Overweight (body mass index greater than 25 kg/m²)
- Habitual physical inactivity
- High-risk ethnicity (African American)
- Hypertension (blood pressure [BP] greater than 140/90 mm Hg)
- High-density lipoprotein concentration less than 35 mg/dL
- Presence of prediabetes (impaired fasting glucose or impaired glucose tolerance)

3. Type 2 DM, uncontrolled, newly diagnosed

4. Lifestyle modifications to improve diet and exercise and metformin (increase metformin to maximal tolerated dose [2550 mg] to increase efficacy)
Activity 3: Glycemic and Nonglycemic Goals

5. Appropriate therapeutic goals for a patient with DM

<table>
<thead>
<tr>
<th>Glycemic Goals</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>FPG</td>
<td>70–130 mg/dL</td>
</tr>
<tr>
<td>PPG</td>
<td>&lt; 180 mg/dL</td>
</tr>
<tr>
<td>Hemoglobin A&lt;sub&gt;1c&lt;/sub&gt;</td>
<td>&lt; 7%</td>
</tr>
</tbody>
</table>

FPG = fasting plasma glucose; PPG = postprandial blood glucose.

<table>
<thead>
<tr>
<th>Nonglycemic Goals</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Blood pressure&lt;sup&gt;a&lt;/sup&gt;</td>
<td>&lt; 130/80 mm Hg</td>
<td></td>
</tr>
<tr>
<td>LDL</td>
<td>&lt; 100 mg/dL</td>
<td>&lt; 70 mg/dL (with CVD)</td>
</tr>
<tr>
<td>HDL</td>
<td>&gt; 40 mg/dL (men)</td>
<td>&gt; 50 mg/dL (women)</td>
</tr>
<tr>
<td>Triglycerides</td>
<td>&lt; 150 mg/dL</td>
<td></td>
</tr>
</tbody>
</table>

<sup>a</sup>Lower blood pressure is appropriate in some patients, depending on additional compelling indications. CVD = cardiovascular disease; HDL = high-density lipoprotein; LDL = low-density lipoprotein.

Activity 4: Type 2 DM Therapeutic Goal

6. The patient’s American Diabetes Association glycemic and nonglycemic goals and the most appropriate agent to recommend at this time are as follows.

<table>
<thead>
<tr>
<th>Therapeutic Goals</th>
<th>Controlled</th>
<th>Uncontrolled</th>
<th>Drug of Choice for Uncontrolled Goals</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPG</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Hemoglobin A&lt;sub&gt;1c&lt;/sub&gt;</td>
<td>X</td>
<td>Sulfonylurea (preferable) or basal insulin (intermediate- or long-acting insulin: 10 units/day or 0.2 unit/kg). Titrate basal insulin to obtain FPG between 70 mg/dL and 130 mg/dL.</td>
<td></td>
</tr>
<tr>
<td>Blood pressure</td>
<td>X</td>
<td>ACEI or ARB</td>
<td></td>
</tr>
<tr>
<td>LDL</td>
<td>X</td>
<td>Statin (~22% reduction desired)</td>
<td></td>
</tr>
<tr>
<td>HDL</td>
<td>X</td>
<td>Statin (~17% increase desired) ± fibrate, niacin, or gemfibrozil</td>
<td></td>
</tr>
<tr>
<td>Triglycerides</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ACEI = angiotensin-converting enzyme inhibitor; ARB = angiotensin receptor blocker; HDL = high-density lipoprotein; LDL = low-density lipoprotein.
Activity 5: Type 2 DM Medications

7. Drug class comparison based on hemoglobin $A_1c$–lowering properties and effect on weight

<table>
<thead>
<tr>
<th>Drug Class</th>
<th>Hemoglobin $A_1c$ % Reduction</th>
<th>Effect on Weight (↑, ↓, or no effect)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amylin analogs</td>
<td>0.5–1</td>
<td>↓</td>
</tr>
<tr>
<td>Dipeptidyl peptidase-4 inhibitors</td>
<td>0.5–0.8</td>
<td>No effect</td>
</tr>
<tr>
<td>GLP-1 analogs</td>
<td>0.5–1.1</td>
<td>↓</td>
</tr>
<tr>
<td>Meglitinides</td>
<td>0.5–1.5</td>
<td>↑</td>
</tr>
<tr>
<td>Metformin</td>
<td>1–2</td>
<td>↓</td>
</tr>
<tr>
<td>Sulfonylureas</td>
<td>1–2</td>
<td>↑</td>
</tr>
<tr>
<td>Thiazolidinediones</td>
<td>0.5–1.4</td>
<td>↑</td>
</tr>
<tr>
<td>α-Glucosidase inhibitors</td>
<td>0.5–0.8</td>
<td>↓</td>
</tr>
</tbody>
</table>

GLP-1 = glucagon-like peptide-1.

Activity 6: Type 2 DM Medications

8. Hold metformin for 48 hours before cardiac catheterization.
    Hold glyburide while the patient is taking nothing by mouth.

9. The patient is showing early signs of renal impairment with an increase in baseline serum creatinine from 0.8 mg/dL to 1.3 mg/dL. Glipizide might be a better option in renal impairment because active metabolites are renally eliminated. He should be initiated on glipizide 5 mg by mouth 2 times/day.

Activity 7: Insulin Review

10. Ranking of insulin products from shortest duration to longest duration, with 1 being the shortest and 5 being the longest in duration

<table>
<thead>
<tr>
<th>Category</th>
<th>Onset</th>
<th>Duration (hours)</th>
</tr>
</thead>
<tbody>
<tr>
<td><em><strong>4</strong></em></td>
<td>Detemir</td>
<td>Long acting</td>
</tr>
<tr>
<td><em><strong>3</strong></em></td>
<td>NPH</td>
<td>Intermediate acting</td>
</tr>
<tr>
<td><em><strong>1</strong></em></td>
<td>Lispro</td>
<td>Rapid acting</td>
</tr>
<tr>
<td><em><strong>5</strong></em></td>
<td>Glargine</td>
<td>Long acting</td>
</tr>
<tr>
<td><em><strong>2</strong></em></td>
<td>Regular</td>
<td>Short acting</td>
</tr>
</tbody>
</table>
Activity 8: Type 1 DM Case Review

11. 15 units of glargine subcutaneously every night; 5 units of aspart subcutaneously before meals 3 times/day

- Total daily dose (TDD) = 0.3–0.6 unit/kg/day (insulin-naive patients, typically 0.5–0.6 unit/kg/day)
- 60 kg x 0.3 unit/kg/day = 18 units
- 60 kg x 0.6 unit/kg/day = 36 units
- Basal/bolus regimen = TDD/2 (50% basal and 50% bolus)
- Basal (glargine or detemira) = 9–18 units
- Bolus (lispro, aspart, or glulisine) = 9–18 units (total bolus dose/3 administered 3 times/day with meals)

Because of interpatient variability, detemir should be administered two-thirds in the morning and one-third at night (duration of action can be as short as 6 hours).

Activity 9: Insulin Adjustment

12. Appropriate period for determining the dose adjustment for self-monitoring of blood glucose (SMBG)

<table>
<thead>
<tr>
<th>Insulin Type</th>
<th>Time of Administration</th>
<th>Appropriate SMBG Time (i.e., FPG, PPG, pre-lunch, lunch, pre-dinner, bedtime, overnight)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NPH</td>
<td>Before breakfast</td>
<td>Pre-dinner (efficacy) Midday/lunch (safety)</td>
</tr>
<tr>
<td></td>
<td>Before dinner</td>
<td>FPG (AM) (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td></td>
<td>At bedtime</td>
<td>FGP (AM) (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td>Regular</td>
<td>Before breakfast</td>
<td>PPG breakfast/pre-lunch (safety/efficacy)</td>
</tr>
<tr>
<td></td>
<td>Before lunch</td>
<td>PPG lunch/pre-dinner (safety/efficacy)</td>
</tr>
<tr>
<td></td>
<td>Before dinner</td>
<td>PPG dinner/HS (safety/efficacy)</td>
</tr>
<tr>
<td>Detemir</td>
<td>Before breakfast</td>
<td>Pre-dinner/HS/FPG ? (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td></td>
<td>Dinner or bedtime</td>
<td>FPG (AM) (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td>Glargine</td>
<td>Bedtime</td>
<td>FPG (AM) (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td></td>
<td>AM</td>
<td>FPG (AM) (efficacy) Overnight (safety)</td>
</tr>
<tr>
<td>Lispro, aspart, glulisine</td>
<td>Before breakfast</td>
<td>PPG breakfast (safety/efficacy)</td>
</tr>
<tr>
<td></td>
<td>Before lunch</td>
<td>PPG lunch (safety/efficacy)</td>
</tr>
<tr>
<td></td>
<td>Before dinner</td>
<td>PPG dinner (safety/efficacy)</td>
</tr>
</tbody>
</table>

AM = morning; FPG = fasting plasma glucose; HS = at bedtime; PPG = postprandial blood glucose; SMBG = self-monitoring of blood glucose.
Activity 10: Insulin Adjustment Review

13. Appropriate adjustments of insulin regimen and rationale

<table>
<thead>
<tr>
<th>Insulin</th>
<th>Dose Adjustment? (Yes or No)</th>
<th>Rationale</th>
<th>Recommended Dose (units)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glargine HS</td>
<td>Yes</td>
<td>FPG consistently above ADA goal for FPG (70–130 mg/dL)</td>
<td>17&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Aspart breakfast</td>
<td>Yes</td>
<td>PPG consistently above ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>7&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Aspart lunch</td>
<td>Yes</td>
<td>PPG consistently above ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>7&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Aspart dinner</td>
<td>No</td>
<td>PPG consistently within ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>5</td>
</tr>
</tbody>
</table>

<sup>a</sup>Adjustments are typically made in 2- to 5-unit increments; however, total adjustment should not exceed 20% of the TDD. ADA = American Diabetes Association; FPG = fasting blood glucose; PPG = postprandial blood glucose; TDD = total daily dose.

Activity 11: Insulin Adjustment

14. Appropriate adjustments of insulin regimen and rationale

<table>
<thead>
<tr>
<th>Insulin</th>
<th>Dose Adjustment? (Yes or No)</th>
<th>Rationale</th>
<th>Recommended Dose (units)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glargine HS</td>
<td>Yes</td>
<td>FPG consistently above ADA goal (70–130 mg/dL). The dose should be decreased because 3 AM blood sugars indicate hypoglycemia. Somogyi effect is the likely etiology of the FPG elevation. Decreasing the dose will result in decreased overnight hypoglycemia and decreased FPG</td>
<td>20–23&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Aspart breakfast</td>
<td>No</td>
<td>PPG consistently within ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>8</td>
</tr>
<tr>
<td>Aspart lunch</td>
<td>No</td>
<td>PPG consistently within ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>8</td>
</tr>
<tr>
<td>Aspart dinner</td>
<td>No</td>
<td>PPG consistently above ADA goal for PPG (&lt; 180 mg/dL)</td>
<td>10–13&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

<sup>a</sup>Adjustments are typically made in 2- to 5-unit increments; however, the total adjustment should not exceed 20% of the TDD. ADA = American Diabetes Association; FPG = fasting blood glucose; PPG = postprandial blood glucose; TDD = total daily dose.
Activity 12: Hypoglycemia Treatment

15. Ingest 15–20 g of glucose:
   • 2 or 3 glucose tablets
   • 1/2 cup (4 oz) of any fruit juice
   • 1/2 cup (4 oz) of a regular (not diet) soft drink
   • 1 cup (8 oz) of milk
   • Five or six pieces of hard candy
   • 1 or 2 teaspoons of sugar or honey

Retest blood sugar in 15 minutes.
   • If greater than 70 mg/dL, eat a meal at an appropriate time.
   • If n is less than 70 mg/dL, ingest a second 15- to 20-g glucose load and continue to retest at 15-minute intervals until corrected.

Activity 13: Thyroid Laboratory Value

16. Laboratory parameters

<table>
<thead>
<tr>
<th></th>
<th>Hyperthyroidism</th>
<th>Hypothyroidism</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSH</td>
<td>↓</td>
<td>↑</td>
</tr>
<tr>
<td>T₃/T₄</td>
<td>↑</td>
<td>↑</td>
</tr>
<tr>
<td>TRH</td>
<td>↓</td>
<td>↑</td>
</tr>
</tbody>
</table>

TRH = thyrotropin-releasing hormone; TSH = thyroid-stimulating hormone; T₃/T₄ = triiodothyronine/thyroxine.

Activity 14: Hyperthyroid Case

17. Methimazole 15 mg by mouth daily and propylthiouracil 100 mg by mouth 3 times/day
   Iodines (Lugol’s solution and saturated solution of potassium iodide)
   β-Blockers (primarily propranolol) for symptomatic control
   Radioactive iodine (131I)

18. Counseling points to discuss with the patient after her ingestion of radioactive iodine include:

   Flush toilet twice after use with the lid down.
   For 3 days, sleep in separate bed and minimize time with children.
   For 5 days, avoid long trips and public transportation.
   For 7 days, minimize close contact with other people.
   For 7 days, keep dishes and clothes separate, and wash immediately.
   For 10 days, avoid pregnant women.
   Do not breastfeed or become pregnant for 6 months.
**Activity 15: Hypothyroid Medications**

19. Agent comparison based on thyroid source and equivalent dose

<table>
<thead>
<tr>
<th>Drug</th>
<th>Thyroid Source</th>
<th>Equivalent Dose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thyroid USP</td>
<td>Desiccated hog, beef, or sheep thyroid</td>
<td>1 grain (64 mg)</td>
</tr>
<tr>
<td>Levothyroxine</td>
<td>Synthetic T₄</td>
<td>100 mcg (0.100 mg)</td>
</tr>
<tr>
<td>Liothyronine</td>
<td>Synthetic T₃</td>
<td>25 mcg (0.025 mg)</td>
</tr>
<tr>
<td>Liotrix</td>
<td>Synthetic T₃/T₄ ratio = 4:1</td>
<td>12.5/50 mcg T₃/T₄</td>
</tr>
</tbody>
</table>

T₃/T₄ = triiodothyronine/thyroxine.

**Activity 16: Hypothyroid Case Review**

20. Levothyroxine 50–75 mcg by mouth daily  
   Liothyronine 25 mcg by mouth daily

21. Levothyroxine 25 mcg intravenously daily (intravenous starting dose is one-half the oral dose)

**Activity 17: Syndrome of Inappropriate Antidiuretic Hormone**

22. The patient has hyponatremia because his serum sodium is 110 mEq/L, and his volume status is euvolemic because there is no evidence of hypovolemia or hypervolemia. The patient's diagnosis is SIADH (syndrome of inappropriate antidiuretic hormone) because of high urine osmolality and high urine sodium.

23. The desired rate of correction of hyponatremia is 0.5 mEq/L/hour.

24. Osmotic demyelination syndrome

25. 3% NaCl (sodium chloride) 700 mL @ 35 mL/hour for 20 hours

Na deficit = (weight)(% TBW [total body weight])(desired Na – measured Na)  
Na deficit = (60 kg)(0.6)(120 mEq/L - 110 mEq/L) = 360 mEq

\[
\text{Volume of intravenous fluid} = \frac{\text{Na deficit}}{\text{concentration of Na in intravenous fluid}} \\
\text{Volume of intravenous fluid} = \frac{360 \text{ mEq}}{514 \text{ mEq/liter}} \times 1000 \text{ mL/L} = 700 \text{ mL}
\]
Time = \frac{\text{desired Na} - \text{measured Na}}{0.5 \text{ mEq/L per hour}} \\
\text{Time} = \frac{10}{0.5} = 20 \text{ hours} \\

\text{Intravenous fluid rate} = \frac{\text{volume of intravenous fluid}}{\text{time for correction}} \\
\text{Intravenous fluid rate} = \frac{700}{20} = 35 \text{ mL/hour}
**Biostatistics and Clinical Trial Design & Interpretation**

**Case 1**

1. The type of data represented by a Likert scale is ordinal. As such, use a nonparametric type of statistical test. In addition, this case describes a pre-post design with the same subjects; therefore, you would need to use a test that takes into account the paired or matched nature of the comparison groups. The Wilcoxon signed rank test should be used with ordinal-level data and matched or paired comparison groups.

2. Each of these outcomes requires the comparison of percentages or proportions between two groups. Again, the subjects in this case serve as their own controls; thus, the data are considered paired or matched. The statistical test that would be used to compare nominal-level data (i.e., proportions) of paired or matched samples is the McNemar test.

**Case 2**

3. To evaluate this statement, recall that the standard error of the mean (SEM) is calculated as the standard deviation divided by the square root of the sample size. When solving this equation for the standard deviation, you get a value of 1. Because about 95% of all population members fall within about 2 SD of the mean, this would mean that the cardiac output of 95% of the population falls between 3 L/minute and 7 L/minute. It would indeed be unusual to observe cardiac outputs outside this range.

4. This interpretation is inconsistent with the data because it is derived using the value for the SEM (i.e., mean cardiac output ± 2 SEM), and the SEM tells us about the precision of the estimate of the mean, NOT the spread in the data.

5. This statement is inconsistent with the data presented because these are continuous data from a normally distributed population; therefore, the mean is the appropriate measure of central tendency.

6. This statement is not consistent with the data because it refers to values corresponding to 1 SD, which would encompass only 68% of all population members. Therefore, about 32% of the population could be expected to have values in this range—a frequency not considered “unusual.”

**Case 3**

7. This statement would not be considered a correct interpretation of the information presented because, for a type I error to have occurred, you must conclude a difference when one does not exist. In this case, with $\alpha$ set at 0.05, there is no statistically significant difference, so there is no possibility of a type I error.
8. This statement is consistent with the data previously presented. Lack of a statistically significant difference is required to make a type II error. Type II errors occur when “no difference” is concluded on the basis of the p-value when, in fact, a true difference between the groups exists. To minimize the risk of a type II error, the power of a trial, by convention, should be greater than 80%. Because power is calculated as $1 - \beta$, setting $\beta$ as less than 0.20 would be necessary to result in a power greater than 80%.

9. As in No. 7, this statement would not be considered a correct interpretation of the information presented because for a type I error to have occurred, you must conclude a difference when one does not exist. In this case, with $\alpha$ set at 0.05, there is no statistically significant difference; thus, there is no possibility of a type I error. In addition, setting $\alpha$ to the even more stringent 0.01 makes it even less likely that a statistically significant difference would be found.

10. This statement is consistent with the data previously presented because setting $\beta$ at more than 0.30 would actually decrease the power to detect a difference. Thus, although a type II error may have occurred, the proposed solution is incorrect.

**Case 4**

11. You can determine whether the result is statistically significant by evaluating the confidence interval and determining the possible values for the difference it contains. If a 95% confidence interval contains within its bounds the value that would represent “no difference,” you can conclude that the results are not statistically significant. Conversely, if a 95% confidence interval excludes the value that would represent no difference, you can conclude that the p-value is less than 0.05 and, thus, that the difference is statistically significant.

   In this case, the difference between hemoglobin A$_{1c}$ is not statistically significant. Note that the confidence interval contains within its bounds the value of zero (i.e., the value representing no difference), and as such, a difference of zero between the hemoglobin A$_{1c}$ values could be the true difference between the groups.

**Case 5**

12. You would need to consider the level of data measurement (e.g., nominal, ordinal, continuous), as well as whether the data are normally distributed and whether the data measurements are from two separate groups or whether they are paired or matched.

13. In this case, the type of comparison described involves a continuous variable using patients as their own control (i.e., matched data). If you convert this continuous variable (AUC) to its natural log, it has a normal distribution. As such, an appropriate statistical test to compare the blood levels of the new medicine with and without the administration of ganciclovir would be a paired t-test.
**Case 6**

14. To determine the answer to this question, first consider which of the investigations found a statistically significant difference between the response rates. You can do this using the data presented by looking at the p-values for each trial.

To help assess clinical significance, consider that, for a trial to be clinically significant, there must be at least a 20% difference in response rates. Because none of the trials excludes the possibility that the true difference in response rate could be less than 20%, none of the trials would be considered clinically significant. You know this because the confidence intervals in all the trials contain values less than 20 within their bounds. As such, even the statistically significant trials cannot be said to ensure that the difference between regimens is at least 20%. The following figure represents this graphically (note that all of the confidence intervals contain values less than 20):

![Graph showing confidence intervals and clinically important difference](image)

**Case 7**

15. Decreasing $\alpha$ would make a type I error less likely. If other study design components were held constant, then decreasing $\alpha$ would increase the sample size needed to conduct your study.

16. Increasing $\beta$ effectively decreases your power to detect differences between groups (remember, power is $1 - \beta$). A decrease in power would indicate you are more willing to miss a difference, even though one may exist. Decreasing sample size is one way to decrease the power of your study.

17. Decreasing the size of the difference you wish to detect would require a larger sample size.

**Case 8**

18. To answer this question, look at the 95% confidence interval. A difference in this example is that, in observational study designs (also known as epidemiologic designs), the value that would indicate no difference between the groups is 1. Because the results of these studies (e.g., case-control, cohort) are reported as relative risks or odds ratios, the value 1 signifies no difference in the risk or odds of an event. In this example, the 95% confidence interval does not include the value representing no difference between the groups (i.e., the value 1), so it can be determined that the results are statistically significant with a p-value less than 0.05.
19. Because the odds ratio is less than 1, administering the vaccine would be said to be associated with a decreased risk or chance of having a myocardial infarction (MI). The odds ratio of 0.7 would mean a 30% decrease in the odds of having an MI, and the 95% confidence interval would indicate that the real difference could be anywhere from a 10% reduction to a 50% reduction.

20. For case-control studies, the cases and controls are selected according to the presence or absence of a disease or outcome. In this example, having or not having the outcome of MI (i.e., the disease) determined the basis for the comparisons. In a cohort trial, the cohorts compared are determined on the basis of the presence or absence of an exposure. Had this been a cohort trial, one possible design would have classified patients on the basis of whether they had received the vaccine and then would have looked back in time, or observed them into the future, to determine whether those exposed had an MI at a rate different from those not exposed to the vaccine.

**Case 9**

21. Randomization is important because it distributes uncontrolled variables evenly among the groups. It reduces or eliminates the influence of bias or confounders as contributing to any observed differences between the groups and serves to isolate the influence or effect of the intervention. In the trial described in this case, randomization could be important to account for differences in illness burden or complexity among practices, or to account for “leakage” of the intervention to the control group. (In other words, those who are not to receive the intervention receive at least part of it because providers in the practice believe in its value and begin to adopt all or part of it for all patients.)

22. A type of randomization known as cluster randomization may be particularly useful for an investigation of this type. Cluster randomization randomizes groups instead of individuals. In this case, the groups would likely be practice sites. This can minimize the chance of leakage of the intervention to patients who are not supposed to be receiving it.

**Case 10**

23. The circles each represent the mean difference (i.e., point estimate) between the intervention and control groups for each trial included in the meta-analysis. The lines through each circle represent the confidence intervals for the mean difference of each of the trials. The diamond at the bottom of the figure represents the results for the estimate of the odds ratio for an asthma exacerbation when summarizing/combing the results of the individual trials. The width of the diamond represents the confidence interval for this summary estimate of effect.

24. For an odds ratio, numbers less than 1 indicate that the outcome of interest is less likely to occur, and numbers greater than 1 indicate that the outcome is more likely to occur.

25. In this example, the new drug appears to have a statistically nonsignificant effect on the number of asthma exacerbations: The estimate of the effect is less than 1, but the confidence interval includes 1 (i.e., no difference) as a possibility.
**Case 11**

26. Statistical heterogeneity exists in a meta-analysis when differences exist between the trials in the areas of randomization, early termination, measures of risk, or existence of publication bias (to name a few). In a basic sense, heterogeneity is an important consideration to make sure that a meta-analysis is comparing “apples to apples.”

27. There are a few common methods to test, statistically, for heterogeneity in a meta-analysis. A $\chi^2$ or a Cochrane $Q$ test is a common statistical technique used to assess heterogeneity. Another test is the $I^2$ test or value.

28. For the $\chi^2$ and Cochrane $Q$ tests, a p-value greater than 0.1 is used as a cutoff. For these tests, a high p-value (i.e., greater than 0.1) indicates no heterogeneity. The $I^2$ test is interpreted in an opposite manner, whereby higher values indicate greater heterogeneity. For this test, values less than 0.25 correspond with low heterogeneity, values of 0.25–0.50 correspond to moderate heterogeneity, and values greater than 0.5 indicate a high level of heterogeneity.

**Case 12**

29. This is a randomized trial, which indicates that the two groups being compared are independent. The outcome of interest, hospitalization for congestive heart failure symptoms, is a dichotomous outcome and is thus a variable that would be considered nominal. In this case, a $\chi^2$ test would be appropriate.

30. In the medication group, 27 of 1232 patients had the outcome of interest. This would equal about 2%. In the placebo group, 42 of 1230 patients had the outcome of interest. This would equal about 3.4% of patients. The relative reduction in the number of events would be (3.4% − 2%)/3.4%. This represents a 41% relative reduction.

31. The absolute reduction in events between the groups is 3.4% − 2%. Thus, the absolute reduction in events is 1.4%.

32. The number needed to treat (NNT) is calculated as the reciprocal of the absolute reduction in events. As such, the NNT would be $1/1.4\% = 1/0.014 = 71$.

**Case 13**

33. The combining of more than one end point into a composite end point has some potential advantages; it 1) alleviates problems of multiple statistical testing, 2) increases event rates, and 3) decreases required sample sizes.
34. There are many potential difficulties in interpreting and working composite end points. Some of these are as follows:
   • Misattribution of statistically beneficial effects of composite measure to each of its component end points
   • Dilution of effects
   • Negative results for relatively common components of composite end points “hide” real differences in other end points.
   • Undue influence exerted on composite end point by “softer” component end points
   • For example, hospitalization, retinopathy, vascular death
   • Problems when component end points go in opposite directions
   • Weighting of end points
   • Should death “count” the same as other end points?
   • End points that combine death and nonfatal events are subject to biases from competing risks.
   • For example, increased death means decreased nonfatal events.

CASE 14

35. Intention-to-treat analysis provides a better estimate of real-world effectiveness because it does not consider adherence. Once patients are randomized to a group (i.e., treatment or placebo), they are analyzed as part of that group regardless of whether they actually adhere to the intervention. This approach to the analysis of clinical trial data has been viewed as providing a conservative estimate of effectiveness that should correspond best with what occurs in practice.

   Per-protocol analysis analyzes only the data from study subjects who are randomized and then complete the treatment according to the protocol. Those who do not adhere to their assigned treatment (usually at some predefined level) are dropped from the analysis. This type of analysis can give a better estimate of the maximal effectiveness for a particular intervention. However, because patients are dropped from the analysis if they do not adhere to the protocol, power issues (i.e., lack of sample size) can become a concern by the end of the trial.

   As-treated analysis, as the name implies, analyzes study participants on the basis of how they were actually treated. If, for example, a trial has active treatment and placebo treatment groups, a patient randomized to active treatment who takes only the first few doses of medicine would, at the end of the trial, be analyzed as a placebo group patient. This approach, compared with per-protocol, minimizes the impact of nonadherent patients on the power by keeping their data in the trial. However, and probably more importantly, this approach is generally considered to greatly jeopardize the benefits of the randomization process and may introduce bias into the analysis.

36. The investigators’ stated purpose is to determine the maximal effectiveness of an intervention when it is used correctly. In this case, a carefully planned per-protocol approach to data analysis would give them the best estimate of maximal effectiveness.
Infectious Diseases in the Ambulatory Care Setting

Case 1

1. Leukocyte esterase, proteinuria, and hematuria are not specific for a urinary tract infection (UTI). Although leukocyte esterase indicates the presence of white blood cells in the urine, this could be a sign of inflammation in the urinary tract. Proteinuria and hematuria could be present in other disease states, also. Nitrite positive indicates the presence of nitrate-reducing bacteria such as Escherichia coli; therefore, it would be most indicative of a UTI.

2. Many options exist for treating an uncomplicated UTI, generally ranging in duration from 3 to 7 days and using many different agents. Antibiotic selection should be based on patient-specific parameters (e.g., allergies) and local sensitivity information.

Possible antibiotic regimens could include the following.

<table>
<thead>
<tr>
<th>Outpatient Antimicrobial Therapy for UTIs in Adults</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Indications</strong></td>
</tr>
<tr>
<td>Uncomplicated UTIs</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

UTI = urinary tract infection.

3. Resolution of symptoms (e.g., dysuria, frequency). Lack of any new symptoms (e.g., fever, rigors). Adverse effects from chosen regimen. In uncomplicated UTIs, follow-up cultures are not routinely performed.

Case 2

4. Significant bacteriuria traditionally has been defined as bacterial counts greater than 100,000 (10^5) colony-forming units (CFU) per milliliter of urine. Many clinicians, however, have challenged this statement as too generalized. Indeed, significant bacteriuria in patients with symptoms of a UTI may be defined as greater than 10^2 organisms per milliliter. Because this patient (R.T.) shows symptoms in the presence of a positive nitrite and 10^3 CFU/mL gram-negative rods, she should be treated for a UTI.
5. In general, R.T. would be considered to have an uncomplicated UTI. As such, a regimen chosen on the basis of patient characteristics from the list of agents in Answer 2 would be appropriate. You should consider whether R.T. is pregnant; if so, your choice of antibiotic may be altered.

6. Although R.T. could be at risk of gonorrhea and/or chlamydia because of having unprotected sex, she does not have vaginal discharge, and her onset of symptoms is within 3 days of sexual contact; the usual onset of symptoms in women takes up to 10 days. A Gram stain and nucleic acid amplification testing (NAAT) would need to be performed by a vaginal swab to determine whether she has gonorrhea or chlamydia before treatment could be initiated.

**Case 3**

7. *Neisseria gonorrhoeae* appears microscopically as gram-negative diplococci. Abnormal vaginal discharge would usually be present at this point (i.e., given the time elapsed since intercourse); however, it is not part of this patient’s history. In addition, NAAT is generally performed to rule out *Chlamydia* infection; however, the results of such testing are not reported in this case.

8. Specific patient characteristics that would have to be considered before choosing an antibiotic therapy include the following:
   - Rule out a particular infection.
   - Medication allergies and/or adverse reactions
   - Pregnancy (or other contraindications, including drug interactions)
   - Cost/adherence
   - Others

9. Empirically, a regimen should cover the causative organisms for both gonorrhea and chlamydia. This patient has several factors that should be considered when choosing her regimen, including a history of penicillin allergy, pregnancy, a potential drug interaction (i.e., birth control pills), and likely economic constraints (i.e., she is a student). Because her penicillin allergy is limited to a rash, the use of cephalosporins would not be strictly contraindicated in her. Further questioning about the type and severity of the rash and the time this reaction occurred can provide additional reassurance with the choice of a cephalosporin. Her positive pregnancy test serves as a contraindication to fluoroquinolones.
   
   A reasonable choice for her empiric treatment would be ceftriaxone 250 mg intramuscularly once, together with azithromycin 1 g by mouth once.

**Case 4**

10. The relative benefits of each of the following agents when considering further treatment for K.M.’s cellulitis are as follows:

   A. Penicillin VK 500 mg by mouth every 6 hours for 10 days
      Cheap; active against *Streptococcus pyogenes* but would not cover *Staphylococcus aureus* (methicillin-sensitive *Staphylococcus aureus* [MSSA] or methicillin-resistant *S. aureus* [MRSA]) or anaerobes
B. Vancomycin 1 g intravenously every 12 hours for 10 days
   Covers most common organisms including *S. pyogenes*, MSSA, and MRSA. However, this drug is invasive and requires some monitoring.

C. Trimethoprim/sulfamethoxazole 1 double-strength tablet by mouth 2 times/day for 10 days
   Provides some coverage of *Streptococcus*, as well as activity against MSSA and most community-acquired MRSAs (CA-MRSAs) for infections like cellulitis. It is generally well tolerated and inexpensive.

D. Dicloxacillin 250 mg by mouth 4 times/day for 10 days
   Good *Streptococcus* and MSSA coverage, but not effective for CA-MRSA

11. Of the options listed, trimethoprim/sulfamethoxazole 1 double-strength tablet by mouth 2 times/day for 10 days appears to be the best choice for coverage, cost, and tolerability. Keep in mind that this could be altered on the basis of local resistance patterns—familiarity with these patterns is essential to guiding antimicrobial therapy for these types of infections.

**Case 5**

12. The following signs and symptoms are consistent with the diagnosis of community-acquired pneumonia:
   - Fever
   - Cough
   - Respiratory rate (?)
   - White blood cell (count)
   - Chest radiography with consolidation

13. Respiratory fluoroquinolone (levofloxacin, moxifloxacin, gemifloxacin)
   - β-Lactam (high-dose amoxicillin 1 g three times/day, amoxicillin/clavulanate 2 g twice daily, or ceftriaxone, cefpodoxime, and cefuroxime 500 mg twice daily) plus a macrolide
   - In regions with a high rate (greater than 25%) of macrolide-resistant *Streptococcus pneumoniae* (erythromycin minimum inhibitory concentration [MIC] of 16 mg/L or greater), use an alternative agent such as fluoroquinolone.

   If MRSA or CA-MRSA is suspected:
   - Add vancomycin or linezolid.
   - Patient may need to be hospitalized.

14. Comorbidities—Diabetes, congestive heart failure
   Renal function would need to be considered in this patient when determining a dose of antibiotic.
CASE 6

15. Pharyngitis has both viral and bacterial causes. The medical literature has shown repeatedly that differentiating between viral and bacterial pharyngitis cannot be done on the basis of clinical symptoms alone. The RAPD technique quickly differentiates viral from bacterial causes and thus can guide treatment.

16. Group A *Streptococcus* remains very susceptible to penicillin; thus, penicillin (or a derivative) remains a first-line treatment. Appropriate treatments would include the following:

   Oral: Penicillin VK 50 mg/kg/day divided into three doses for 10 days (adults 500 mg 2 times/day)
   Amoxicillin 40–50 mg/kg/day divided into three doses for 10 days (adults 500 mg 3 times/day)
   Macrolides, or first-generation cephalosporins, remain good alternatives given the patient’s characteristics (e.g., allergy).

CASE 7

17. Amoxicillin 500 mg – 1 g 3 times/day

18. In patients with sinusitis and allergies to penicillins and/or cephalosporins, many other possible antibiotics can cover the common causative organisms of acute sinusitis. These include trimethoprim/sulfamethoxazole, azithromycin or clarithromycin, and “respiratory” fluoroquinolones (e.g., levofloxacín, moxifloxacín, gemifloxacín).

19. Although decision points for antibiotic failure in acute sinusitis are not always well defined, a patient who experiences no change in symptoms after 6 days of therapy may be considered for alterations in treatment (i.e., treatment failure). In this circumstance, choose an agent that will have activity for the organisms most likely to be resistant to the first-line agents. In this case, such choices would include the following: second-generation cephalosporin (not a choice for this patient because of the patient’s allergies); respiratory fluoroquinolones; and high-dose amoxicillin/clavulanate. For resistant *S. pneumoniae*, choices include high-dose amoxicillin, clindamycin, or a respiratory fluoroquinolone.

CASE 8

20. Diabetes mellitus—Neuropathy, ischemia (atherosclerosis), immunologic changes caused by diabetes

21. The pros/cons of each of the following antibiotic therapies when considering F.H.’s case are as follows:

   A. Trimethoprim/sulfamethoxazole
      Not reliable against *Streptococcus* (especially in complicated infections), does not cover anaerobes or *Pseudomonas*
2. Given that many diabetic foot infections are polymicrobial, as well as the foul-smelling description in F.H.’s case and the patient’s renal function, levofloxacin 750 mg every 48 hours would be a reasonable choice because it covers most of the suspected organisms. Although it is not active against a broad range of anaerobes, levofloxacin has some activity against the anaerobes usually found in these types of infections. Some clinicians would consider adding metronidazole given the physical findings (e.g., smell).
Infectious Diseases in the Inpatient Setting

Case 1

1. This patient has community-acquired pneumonia requiring hospitalization and admission to a general medicine floor. Because of this, he should receive either a respiratory fluoroquinolone or ampicillin, ceftriaxone, or cefotaxime plus a macrolide, such as azithromycin. Intravenous therapy should be used to start the transition to oral therapy when clinically indicated.

2. Main features include the following.

<table>
<thead>
<tr>
<th>Pneumonia Subtype</th>
<th>Main Features</th>
</tr>
</thead>
</table>
| Health care associated (HCAP) | • Developing in a patient who was hospitalized in an acute care hospital for 2 or more days within 90 days of the infection; who resided in a nursing home or long-term care facility; who received intravenous antibiotic therapy, chemotherapy, or wound care within the past 30 days of the current infection; or who attended a hospital or hemodialysis clinic  
  • Possible risk of *Pseudomonas, S. aureus*, and other resistant gram-negative organisms |
| Hospital acquired (HAP)    | • Occurs 48 hours or more after admission and is not incubating at the time of admission  
  • Risk of *Pseudomonas, S. aureus*, and other resistant gram-negative organisms |
| Ventilator associated (VAP) | • Arises more than 48–72 hours after endotracheal intubation  
  • Risk of *Pseudomonas, S. aureus*, and other resistant gram-negative organisms |

3. The Joint Commission’s core measures for the management of pneumonia include the following. Many of these can be addressed by use of preprinted order sets and pharmacists’ documentation of assessment in the medical record, particularly for vaccinations. Antibiotic stewardship programs may also play a large role in this process for the antibiotic-associated outcomes.

Measure Short Name
- PN-2 Pneumococcal Vaccination
- PN-3a Blood Cultures Performed Within 24 Hours Before or 24 Hours After Hospital
- Arrival for Patients Who Were Transferred or Admitted to the ICU Within 24 Hours of Hospital Arrival
- PN-3b Blood Cultures Performed in the Emergency Department Before Initial Antibiotic Received in Hospital
- PN-4 Adult Smoking Cessation Advice/Counseling
- PN-5 Antibiotic Timing (Median)
- PN-5c Initial Antibiotic Received Within 6 Hours of Hospital Arrival
- PN-6 Initial Antibiotic Selection for CAP in Immunocompetent Patient
- PN-6a Initial Antibiotic Selection for CAP in Immunocompetent – ICU Patient
- PN-6b Initial Antibiotic Selection for CAP Immunocompetent – Non-ICU Patient
- PN-7 Influenza Vaccination
Case 2

4. This patient is considered to have a complicated pyelonephritis because of existing immunosuppression and should receive empiric intravenous antibiotic therapy with a fluoroquinolone or an extended-spectrum β-lactam. Aminoglycosides should be avoided because of the presence of chronic kidney disease (CKD).

5. Because this patient is symptomatic, the presence of a long-term indwelling catheter would not change antibiotic management; however, the catheter would most likely be replaced with a new one during the treatment course.

6. If the patient is male, then assessing for the presence of prostatitis is indicated because this would dictate a longer treatment course, preferably with a fluoroquinolone.

Case 3

7. This patient would meet the criteria for severe disease on the basis of a serum creatinine greater than 1.5 times the baseline value and a white blood cell count greater than 15,000/mm³.

8. Initial episodes of severe disease should be treated with vancomycin 125 mg 4 times/day for 10–14 days according to the IDSA (Infectious Diseases Society of America) guidelines.

9. The sensitivity should be calculated as follows:

\[
\text{Sensitivity} = \frac{710}{(710 + 185)} = 70\%.
\]

<table>
<thead>

Case 4

10. According to the endocarditis treatment guidelines, the recommended treatment for *Streptococcus viridans* with an MIC (minimum inhibitory concentration) greater than 0.12 mcg/mL with a prosthetic valve is penicillin G plus gentamicin for 6 weeks. Because the patient has CKD, the use of an aminoglycoside may be prohibited. If one is used, however, close monitoring of the renal function should be performed.

11. For future dental procedures, the patient should receive amoxicillin 2000 mg 1 hour before the procedure according to the guidelines.
Activity 1: Hypertension (HTN) Medication

1. MOST appropriate JNC 7 (Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure) first-line drug class for each of the patient vignettes

<table>

</table>

ACE = angiotensin-converting enzyme; BP = blood pressure; CKD = chronic kidney disease; HR = heart rate; STEMI = ST-segment elevation myocardial infarction.

Activity 2: HTN Case

2. This patient has one compelling indication (Framingham risk greater than 10%) resulting in a BP goal of less than 130/80 mm Hg.

3. Nonpharmacologic lifestyle modifications include weight reduction, DASH (Dietary Approaches to Stop Hypertension) diet, dietary sodium restriction (sodium intake, less than 2.4 g), and physical activity (at least 30 minutes most days of the week). The drug of choice in patients with high coronary artery disease (CAD) risk is an angiotensin-converting enzyme inhibitor.

Activity 3: Hyperlipidemia Medication Review

4. Agent comparison based on their lipid-lowering properties

<table>
<thead>

HDL = high-density lipoprotein; LDL = low-density lipoprotein.
**Activity 4: Hyperlipidemia Case**

5. The patient has three National Cholesterol Education Program (NCEP) risk factors including age (older than 45 years), HTN, and cigarette smoking. Patients with two or more NCEP risk factors, as well as a 10-year CHD risk between 10% and 20%, have a low-density lipoprotein (LDL) goal of less than 130 mg/dL. His current LDL concentration is 161 mg/dL, and he requires a 20% reduction.

6. Nonpharmacologic lifestyle modifications include weight reduction, dietary changes, and physical activity (at least 30 minutes most days of the week). The drug of choice in patients with elevated LDL is an HMG-CoA reductase inhibitor.

**Activity 5: Peripheral Arterial Disease Medication Review Key**

7. Agent comparison

<table>
<thead>
<tr>
<th>Medications</th>
<th>Dose</th>

<td>IC</td>
<td>Leg pain</td>
</tr>
</tbody>
</table>

CV = cardiovascular; IC = intermittent claudication; PAD = peripheral arterial disease.

**Activity 6: Peripheral Arterial Disease Case**

8. The patient has an estimated ankle/brachial index (ABI) of 0.73 (right leg) with no signs or symptoms of vascular ischemia. This presentation is consistent with peripheral arterial disease. An ABI of less than 0.90 is consistent with arterial disease resulting in reduced blood perfusion.

9. Peripheral arterial disease should be managed with antiplatelet therapy to reduce cardiovascular risk. Either aspirin 75–325 mg by mouth daily or clopidogrel 75 mg by mouth daily can be recommended.
Activity 7: Stable Angina Medication Review

10. Agent comparison

<table>
<thead>
<tr>
<th>Agent</th>

<td>↓</td>
</tr>
</tbody>
</table>

ACC/AHA = American College of Cardiology/American Heart Association.
Activity 11: Heart Failure Case

15. Decrease lisinopril to 10 mg by mouth daily. The vasodilator therapy should be down-titrated when hypotensive symptoms are related to a recent up-titration of a β-blocker. A decrease in metoprolol XL (extended release) to 25 mg by mouth daily should be considered if the down-titration of the vasodilator therapy fails. The benefits of a β-blocker are well recognized, so if hypotension alone is the problem, the dose of ACE inhibitor should be lowered first. An increase in furosemide to 80 mg by mouth daily is not recommended at this time because of the patient’s low BP and lack of hypervolemic symptoms.

16. The discharge activity that meets the 2005 ACC/AHA Heart Failure Performance Measures is Answer C: Provide discharge counseling on cardiac medications.

Activity 12: Atrial Fibrillation Case

17. Patient’s CHADS2 score:
   • Congestive heart failure = 1 point
   • Hypertension = 1 point
   • Age > 75 years = 0 point
   • Diabetes = 0 point
   • Previous stroke = 0 point
   • 2 points

18. A stroke prophylaxis plan for this patient and the most appropriate dose of each agent are as follows:

<table>
<thead>
<tr>
<th>Aspirin</th>
<th>Warfarin</th>
<th>Dabigatran</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not indicated with a CHADS score of 2 or greater (81–325 mg/day)</td>
<td>Dose adjusted to INR 2–3</td>
<td>150 mg 2 times/day</td>
</tr>
</tbody>
</table>

CHADS = congestive heart failure, hypertension, age older than 75 years, diabetes, previous stroke; INR = international normalized ratio.

19. Amiodarone 400 mg 2 or 3 times/day x 2 weeks; then 400 mg/day for 4 weeks, followed by 200 mg/day. Amiodarone is indicated in patients with atrial fibrillation and systolic heart failure. Dofetilide can also be used in this situation; however, the baseline QTc interval is greater than 440 milliseconds.

Activity 13: Anticoagulation Medication Review

20. Clotting factors inhibited by each of the listed agents:
   • Unfractionated heparin – factor II and X
   • Dalteparin – factor II and X
   • Rivaroxaban – factor X
   • Argatroban – factor II
Activity 14: Intravenous Heparin Titration and Monitoring

21. Decrease infusion rate by 2 units/kg/hour.

   Initial bolus:
   \[(80 \text{ units/kg}) \times 70 \text{ kg} = 5600 \text{ units}\]

   Initial infusion:
   \[(18 \text{ units/kg/hour}) \times 70 \text{ kg} = 1260 \text{ units/hour} \text{ (round to 1250 units/hour)}\]

   New infusion rate = \[1250 \text{ units/hour} - [(2 \text{ units/kg/hour}) \times 70 \text{ kg}]\]
   = 1250 units/hour − [140 units/hour]
   = 1110 units/hour (round to 1100 units/hour)

Activity 15: Warfarin Monitoring and Titration

22. The MOST appropriate recommendation for this patient is Answer C: Decrease to warfarin 6 mg by mouth daily.

   The patient's INR is supratherapeutic at 4.5 with an INR goal of 2.5. The patient is not experiencing signs or symptoms of bleeding and has an INR of less than 5.0, so a reversal agent is not required. One or two doses of warfarin should be held, and the total weekly dose should be decreased by 10%–15%.

   • \[7 \text{ mg/day} \times 7 \text{ days} = 49 \text{ mg/week}\]
   • \[49 \text{ mg} \times 10\% = 4.9 \text{ mg} = \sim5\text{-mg/week reduction}\]
   • \[49 \text{ mg} \times 15\% = 7.35 \text{ mg} = \sim7\text{-mg/week reduction}\]
   • \[49 \text{ mg} - 5 \text{ mg} = 44 \text{ mg/week}\]
   • \[49 \text{ mg} - 7 \text{ mg} = 42 \text{ mg/week}\]
   • \[44 \text{ mg/7 days} = 6.3 \text{ mg/day} = \sim6 \text{ mg/day}\]
   • \[42 \text{ mg/7 days} = 6 \text{ mg/day}\]
1. This patient presents with troublesome gastroesophageal reflex disease (GERD) symptoms that frustrate him. Given that the symptoms occur after meals and are improved with positional changes makes GERD most likely. The patient's amlodipine and metformin could be causing increased symptoms as well. Initiation of targeted lifestyle modifications, including dietary changes and weight loss, should be recommended. Initiation of acid-suppressive therapy would also be appropriate. Because this patient has symptoms more often than 2 days/week, use of a proton pump inhibitor (PPI) on a scheduled basis would be recommended. Given the patient's age, he would also be appropriate to refer for endoscopy, particularly if he does not respond to therapy.

2. This patient presents with symptoms that may be consistent with GERD. Because she has symptoms only 1 or 2 days/week, she may be able to use an on-demand therapy, with either an antacid or a histamine receptor antagonist. Low-dose PPI therapy would also be acceptable as an alternative strategy. The patient has end-stage renal disease, so avoidance of magnesium- and aluminum-containing products would be preferred. Calcium-based antacids may be preferred. If a histamine receptor antagonist were used, appropriate dosing on the basis of renal function would be needed. Cimetidine should be avoided because of a potential interaction with clopidogrel. Likewise, if a PPI were used, avoidance of omeprazole and esomeprazole would be preferred to prevent reductions in clopidogrel effectiveness.

3. The PPIs have been associated with several types of adverse effects with long-term use. These include risk of infection such as pneumonia and Clostridium difficile; increased risk of fracture; reductions in serum magnesium; and anemia. This patient has esophagitis, for which PPIs are the best therapy. The risk of the potential adverse effects previously listed has generally been reported with odds ratios of 1–2.5, with most studies being observational or retrospective. For this patient, the benefit of using the PPI would outweigh the risk. Because the patient is not at high risk of fracture, she should not require calcium or vitamin D supplementation, although measurement of a serum vitamin D concentration could be performed.

4. This patient would be considered high risk because of the presence of two or more risk factors, including age older than 65 years, use of corticosteroids, and use of high-dose NSAID (nonsteroidal anti-inflammatory drug) therapy.
5. Potential pros and cons of these *H. pylori* treatment regimens include the following.

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Pros</th>
<th>Cons</th>
</tr>
</thead>
</table>
| Amoxicillin/clarithromycin + PPI | • Less pill burden than quadruple therapy | • Potential for reduced effectiveness because of high rates of clarithromycin resistance  
• Cannot use in patients with penicillin allergy  
• Drug interactions and adverse effects with clarithromycin (dyspepsia, metallic taste)  
• Requires 14 days of therapy for maximal effectiveness |
| Bismuth + metronidazole + tetracycline + PPI | • Generally more effective than triple therapy  
• Can use in patients with penicillin allergy  
• Metronidazole resistance can be overcome with increases in dose | • Higher pill burden than triple therapy  
• Adverse effects with bismuth (dark stool) and metronidazole (nausea, metallic taste), tetracycline (photosensitivity)  
• Requires 14 days of therapy for maximal effectiveness |

PPI = proton pump inhibitor.

6. This patient should have received at least 10–14 days of therapy according to the treatment guidelines. Retesting for eradication of *H. pylori* should be performed no sooner than 4 weeks after treatment to prevent false-negative tests. The serum IgG (immunoglobulin G) test should not be used for retesting because it remains positive, even after eradication. Use of the urea breath test or fecal antigen test is preferred. Thus, this patient should be retested in at least another 2 weeks using the urea breath test or fecal antigen test.

7. This patient would be at risk of stress-related mucosal bleeding (SRMB) and would require preventive therapy because of the presence of coagulopathy (INR [international normalized ratio] greater than 1.5), one of the two major independent risk factors for SRMB. The patient also has hepatic failure, which is additive in risk.

8. Potential pros and cons of these treatment regimens for encephalopathy include the following.

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Pros</th>
<th>Cons</th>
</tr>
</thead>
</table>
| Lactulose | • Inexpensive  
• Proven efficacy  
• Flexible dosing | • Not well tolerated because of titration on the basis of stool frequency  
• May not be palatable to some patients  
• Requires many doses a day  
• May be combined with other agents |
| Neomycin | • Inexpensive  
• Proven efficacy similar to lactulose  
• Minimal absorption | • Requires many doses a day  
• Possible risk of nephrotoxicity in patients with CKD  
• May be combined with other agents |
| Rifaximin | • Efficacy similar to that of lactulose and neomycin  
• Minimal absorption  
• No risk of nephrotoxicity | • Expensive  
• FDA approved only for prevention  
• 2 or 3 times/day dosing  
• Widespread use may promote resistance |

CKD = chronic kidney disease; FDA = U.S. Food and Drug Administration.
9. This patient has evidence of portal hypertension because of the presence of esophageal varices and ascites. The patient, who has undergone variceal band ligation, should receive therapy to prevent variceal bleeding. Nonselective β-blockers are preferred; however, given the presence of asthma, they would be a contraindication. This patient would need to have an annual screening endoscopy with variceal band ligation as the preventive therapy of choice. For management of ascites, the patient should receive diuretic therapy, preferably with furosemide and spironolactone at a starting dose of 40 mg/100 mg. The patient’s ascetic fluid does not meet the criteria for spontaneous bacterial peritonitis, so antibiotic therapy is not indicated.

10. Calculation of the positive predictive value would be as follows:

\[
\frac{340}{(340 + 32)} \times 100 = 91\%. 
\]
PULMONARY DISEASES

CASE 1

1. Using the National Heart, Lung and Blood Institute (NHLBI) guidelines, this patient would be classified as having moderate persistent asthma. This is based on the most severe category of classification using his forced expiratory volume in 1 second ($\text{FEV}_1$) of 68% of predicted.

2. Exposure to potential environmental triggers, family history, and insurance status may be useful information for making an assessment and a plan.

3. The NHLBI guidelines recommend initiating treatment at step 3, with the preferred treatment being a low-dose inhaled corticosteroid (ICS) plus a long-acting $\beta$-agonist (LABA) OR a medium-dose ICS alone. Given the recent safety concerns with LABAs, it would be preferable to initiate a medium-dose ICS (see Table 5 of Pulmonary Diseases chapter). The patient would also need a short-acting $\beta$-agonist (SABA) as needed for rescue. Modification of trigger exposure and construction of an action plan would also be preferred.

CASE 2

4. Using the NHLBI guidelines, this patient would be classified as having a life-threatening asthma exacerbation on the basis of her minimal response to a SABA and her $\text{FEV}_1$ of less than 25% of predicted.

5. This patient should receive oxygen with a nebulized SABA plus ipratropium as well as a dose of intravenous corticosteroids, such as methylprednisolone, with continuous oxygen saturation monitoring.

6. Both the NHLBI guidelines for asthma and the GOLD (Global Initiative on Obstructive Lung Disease) guidelines for COPD have adopted the use of the following rating scale to rate the strength of evidence. Not all guidelines use the same rating scale to grade evidence. Clinicians need to familiarize themselves with the scale to be used for the respective guideline to accurately interpret the recommendations. Therapeutic recommendations should be made using the highest level of evidence, if possible; however, based on the body of evidence, data may be limited, requiring the use of clinical judgment.

<table>
<thead>
<tr>
<th>Evidence Category</th>
<th>Sources of Evidence</th>

</tr>
</tbody>
</table>
**Case 3**

7. Assessment of inhaler technique, presence of potential adverse effects, ability to afford the medication given the loss of work, and continued exposure to potential environmental triggers would be helpful in assessing this patient’s control.

8. This patient would be classified as not well controlled on the basis of SABA use greater than 2 times/week. This patient is using a low-dose ICS (beclomethasone 160 mcg/day), which is consistent with step 2 therapy according to the NHLBI guidelines. Recommendations for patients who are not well controlled are to increase to the next step of therapy. Options include adding a LABA or increasing to a medium dose of the ICS. Given the recent safety concerns with LABAs, it would be preferable to increase to a medium dose of beclomethasone.

**Case 4**

9. This patient would be classified as stage III (severe) on the basis of an FEV₁/FVC (forced vital capacity) of less than 70% and an FEV₁ between 30% and 50% of predicted.

10. A complete plan for this patient would include the initiation of a SABA as needed with one or more long-acting bronchodilators. Tiotropium would be a viable option for this patient for a long-acting agent. Use of an ICS would not be helpful unless she had repeated exacerbations. The patient should be educated on the proper use of inhalers. Assessment for pneumococcal and influenza vaccinations, initiation of smoking cessation, use of home oxygen therapy, and potential referral for pulmonary rehabilitation would be preferred as well.

11. This patient would be considered to have a moderate-severe exacerbation on the basis of her oxygen saturation of less than 90% and tachypnea. The patient was admitted to a general medicine floor for management and did not require admission to an intensive care unit or have a need for mechanical ventilation.

12. The patient should receive oxygen therapy and a nebulized SABA plus an anticholinergic, as well as administration of an oral corticosteroid at a dose of 40–60 mg/day of prednisone. Use of antibiotics would not be indicated because only two of the three cardinal symptoms are present (dyspnea and increased sputum volume). Had increased sputum purulence been present, antibiotics would have been indicated.
